

Abstract

The purpose of this study was to determine if there were differences in the prevalence of risk factors for low back pain between two groups of nurses. The first group consisted of nurses who had no history of low back pain and the second group consisted of nurses who had a history of low back pain. A questionnaire was distributed to all participants asking about their demographic information, work environment, and lifestyle habits. The results showed that there were significant differences between the two groups in terms of age, years of experience, and frequency of lifting heavy objects. The findings suggest that nurses with a history of low back pain are more likely to have older ages, longer years of experience, and higher frequencies of lifting heavy objects compared to those without such history.
